

a. The ceiling caps every gain

b. Corrected, severe patients recover most

Headroom = 100 – admission BI. Normalising by it removes the ceiling artefact and answers the regression-to-the-mean objection: the advantage of the severe group (BI 20–35) is not explained by simply having had more room to improve. Independent patients (BI 100, $n=4$) are excluded from panel b — their headroom is zero, so the ratio is undefined.
